

Dual buck inverter output voltage frequency

Overview

For the positive half-cycle of the output voltage ($V_o > 0$), S1 and S2 operate at high frequency, whereas S3 is kept ON, and S4 is kept OFF. Generating a negative output voltage rail from a positive input voltage rail can be done by reconfiguring an ordinary buck regulator. The result is an inverting buck-boost (IBB) topology implementation. This application report gives details regarding this conversion with examples. This forms a. The proposed dual-buck inverter uses hybrid unipolar modulation and a topology that is modified from the standard full-bridge dual-buck inverter to address the common mode voltage concerns. In the proposed design, the fast-switching side of the inverter is identical to a half-bridge dual-buck. The simulation experiment results denote that the proposed method can promote the double buck circuit full bridge inverter with good output voltage tracking performance, strong stability and high precision. A switching frequency of 400 kHz is achieved with the adoption of the SiC power device.
